Basement - ground Zero

Dark matter is the dominant component of Galaxies and is an essential ingredient to understand Galaxy properties and Galaxy formation.

Dark matter and Galaxy Formation must be treated in an cosmological context.

The nature (the type) of Dark Matter and the cosmological model need to be explicitated when discussing galaxies and galaxy formation.

All the building of galaxy formation depends on the nature of Dark Matter.
UPDATE and CLARIFICATIONS

ΛCDM agrees with CMB + LSS  BUT
ΛCDM DOES NOT agree with SSS (GALAXIES)

ΛWDM agrees with CMB + LSS + SSS (GALAXIES)
The Standard Model of the Universe is LWDM =
{GR, Newtonian Gravity, Field Theory, QFT}

Sentences like « CMB confirms the ΛCDM model … »
Must be completed by adding: « in the large scales” »
and must be updated with the sentence:
CMB confirms the ΛWDM model in large scales

NEW: Gravity and Quantum Mechanics in Galaxies. Newton, Fermi and Dirac meet together in Galaxies because of keV WDM
2016 DARK MATTER UPDATE

• THERE IS NO CUSP/CORE problem:
  • Observed Galaxy profiles are cored.
  • WDM Galaxy density profiles are cored

• THERE IS NO satellite problem
  • WDM abundance of structures agrees with observations

• In addition, these are not fundamental problems.
  NO DM WIMPS, NO DM annihilation,
  NO DM axions. NO DM bosons
AWDM Cosmology

(I) The Standard Model of the Universe Includes Inflation

(II) THE NATURE OF DARK MATTER IN GALAXIES
from Theory and Observations: Warm (keV scale) DM

(III) NEW: THE ESSENTIAL ROLE OF QUANTUM PHYSICS IN WDM GALAXIES:
Semiclassical framework: Analytical Results and Numerical (including analytical) Results
Observed Galaxy cores and structures from Fermionic WDM and more results.

(IV) NEW: The generic Galaxy types and properties from a same physical framework: From quantum (compact, dwarfs) to classical (dilute, large) galaxies. Equation of state Generalized Eddington approach to galaxies
de Vega Sanchez – Theory Approach to Galaxy Structure

FERMIONIC QUANTUM WDM and GRAVITATION DETERMINE THE OBSERVED PHYSICAL GALAXY STRUCTURE

-> Dark matter (DM): main component of galaxies.
Quantum mechanics: cornerstone of physics from microscopic to macroscopic systems: quantum liquids He3, white dwarf stars, neutron stars. NOT Exotic Physics.

-> Quantum mechanics also responsible of galaxy structures at the kpc scales and below: near the galaxy center, below 10 - 100 pc, the DM quantum effects important for warm DM (WDM), that is for DM particles with masses in the keV scale.
DdVS (New Astronomy 2013)

-> Approach to galaxy structure with results in remarkable
(i) Dwarf galaxies are quantum macroscopic objects for WDM supported against gravity by the WDM fermion pressure

(ii) Theoretical analytic framework based on Thomas-Fermi approach determine galaxy structure from the most compact dwarf galaxies to the largest dilute galaxies (spirals, ellipticals).

The obtained galaxy mass, halo radius, phase-space density, velocity dispersion, are fully consistent with observations.

(iii) Interestingly enough, a minimal galaxy mass and minimal velocity dispersion are found for DM dominated objects, which in turn imply an universal minimal mass $m_{\text{min}} = 1.9$ keV for the WDM particle.
- **OBSERVED GALAXY CORES vs CDM CUSPS and WDM CORES**

- Well established sets of astronomical observations show that the DM galaxy density profiles are cored, that is, profiles which are flat at the center.

On the contrary, **N-body CDM simulations exhibit cusped density profiles**, with a typical $1/r$ cusped behaviour near the galaxy center $r = 0$.

Classical Physics **N-body WDM simulations exhibit cores** but with sizes much smaller than the observed cores.

We have recently developed a new approach to this problem thanks to **Quantum Mechanics**.

- **Fermions** always provide a non-vanishing pressure of quantum nature due to the combined action of the Pauli exclusion principle and Heisenberg uncertainty principle.

- **Quantum effects for WDM fermions rule out** the presence of galaxy cusps for WDM and enlarge the classical core sizes because their repulsive and non-local nature extend well beyond the small pc scales.

- **Smoothing the density profile at the central regions** has an effect on the whole galaxy halo.
THE MINIMAL GALAXY MASS
A minimal galaxy mass and minimal velocity dispersion are found.

This in turn implies a minimal mass $m_{min} = 1.91$ keV for the WDM particle.

This minimal WDM mass is a universal value, independent of the WDM particle physics model because only relies on the degenerate quantum fermion state, which is universal whatever is the non-degenerate regime.

These results and the observed halo radius and mass of the compact galaxies also provide further indication that the WDM particle mass $m$ is approximately around 2 keV.

More precise data will make this estimation more precise.
WDM THEORY OF GALAXIES
REPRODUCES THE OBSERVED GALAXY STRUCTURES
*Gravity and Quantum Mechanics meet together in Galaxies*

de Vega, Salucci, Sanchez  MNRS 2014 reproduced the main observed properties of galaxies of all types, masses and sizes, as the rotation curves, density profiles, phase space density, and scaling relations between the galaxy masses, sizes and velocities, with a physical theory to galaxy structure which captures the essential ingredients of galaxies: **dark matter and gravity.**

*Newton, Fermi and Dirac, meet together in Galaxies through Warm Dark Matter*

This new framework requires dark matter particles to be fermionic with mass in the scale of thousands electron Volts (keV "warm dark matter") and described by their quantum mechanical properties, as their quantum pressure resulting from the combination of the Pauli exclusion principle and the Heisenberg uncertainty principle. Compact dwarf galaxies are thus near the Fermi gas degenerate regime, while large dilute galaxies are in the classical gas Boltzmann regime.

This approach corresponds to the Schrödinger equation in the large number of particles regime and is for galaxies the analogue of the Thomas-Fermi approach for atoms, with gravitation instead of the electric potential.
**Universal rotation curves and Universal density profiles: The same for all galaxies**

The theoretically obtained galaxy rotation curves and density profiles reproduce extremely well the observational curves from ten different and independent sets of data for galaxy masses from $5 \times 10^9$ solar masses until $5 \times 10^{11}$ solar masses.

Remarkably enough, the normalized theoretical circular velocities and density profiles are universal (URC): they are the same for all galaxies of different types, sizes and masses, and they agree extremely well with the observational curves described by cored profiles (flat smooth profiles at the center) and their sizes.

Interestingly enough, small deviations from the exact scaling relations show up for compact dwarf galaxies as a manifestation of the quantum macroscopic effects present in these galaxies.

**Robust Results**

Results of this work are independent of any particular warm dark matter particle physics model, they only follow from the self-gravitation of the warm dark matter particles and their fermionic nature. These important results show the ability of this approach to describe the galaxy structures. They also show that baryonic corrections are not very important to warm dark matter, consistent with the fact that dark matter is in average at least six times more abundant than baryons. The fraction of dark matter over the total mass of galaxies goes from the 95% for large dilute galaxies till 99.99% for dwarf compact galaxies. The baryon fraction in large galaxies can only reach values up to 5%.

**Reference:**

Newton, Fermi and Dirac, meet together in Galaxies through keV Warm Dark Matter

Rotation curves (left panel): The theoretical curves for 10 different galaxy masses all fall one into each other providing an Universal Rotation Curve (URC) which remarkably coincides with the observed universal curve (displayed in red). Small deviations show up only at distances outside twice the radius.

The right panel shows the density profiles for the 10 galaxy masses: All fall into the same and universal density profile which reproduces the observed universal density profile and its size (in red). Interestingly enough, small deviations show up for compact dwarf galaxies as a manifestation of the quantum macroscopic effects predicted in these galaxies, and which can be further tested by next observations. (Examples of other macroscopic objects in nature are dwarf stars, neutron stars and the liquid Helium 3).
The equation of state of galaxies

We have derived the equation of state of galaxies, that is the relation between pressure and density, and provided its analytic expression:  
\[ P(r) = \frac{V^2(r)}{\rho(r)} \]

Two regimes for galaxies emerge:

(i) Large dilute galaxies for \( M_h > 2.3 \times 10^6 \) Msun and effective temperatures \( T_0 > 0.017 \) K described by the classical Boltzmann gas selfgravitational with local ideal gas equation of state at each point (r-dependent).

(ii) Compact dwarf galaxies for \( 1.6 \times 10^6 \) Msun > \( M_h > M_{h, \text{min}} = 30000 \) (2keV / m) \( 16/5 \) Msun, \( T_0 < 0.011 \) K described by the fermion WDM quantum regime with an equation of state more xxxx raide near (but not at) the degenerate state. In particular, the deneredated limit \( T_0 = \) or extreme quantum limit yields the more compact and smallest galaxy. Moreover, in the dilute regime: the halo radius \( r_h \), the \( v^2 \) and the temperature \( T_0 \) show scaling laws in terms of \( M_h \). The amplitudes of these analytic scaling laws have been computed too.
The normalized density and velocity profiles are universal functions of $r / r_h$. Thus, the scaling laws and the universality appearing in the dilute classical regime of large galaxies are linked to the ideal gas behaviour of WDM in this regime.

These results and the theoretical rotation curves remarkably reproduce for $r < r_h$ the galaxy observations.

In the compact regime of small galaxies the equation of state depends on the mass of each galaxy, the density and velocity profiles are not anymore universal, this reflects the quantum physics of the WDM fermions in the compact regime (which generically are near but not at exactly the degenerate limit-state).
The Distribution Function of Dark Matter

→ We developed inverse methods allowing to determine the distribution function \( f(E) \) from the real density profiles obtained from observations or from numerical simulations:

→ Thus, we have found the distribution function \( f(E) \) of galaxy DM halos and the corresponding equation of state from the DM observed density profiles.

→ That is to say, we have solved for galaxies the analogue of the integral Eddington equation of the gaz of stars in globular clusters. The observed density profiles are a realistic starting point, thus the \( f(E) \) obtained from them are realistic functions.
NEW RESULTS

(i) CORED density profiles \( \rho(r \to 0) \to \rho(0) - Kr^2 \) produce distribution functions which are finite and positives at the center, while cusped density profiles with "cusps" growing as \( 1/r \) or more, always produce distribution functions which are divergent at the center.

(ii) The observed CORED density profiles produce distribution functions which are very near the THERMAL Boltzmann distributions for \( r < 3r_h \). (\( r_h \) being the halo radius).

(iii) The analytic expressions for the dispersion velocity and the pressure are derived, they verify the ideal gaz equation of state for the DM with a local temperature \( T(r) = mv^2 (r) / 3 \).

\( T(r) \) is slowly variable and turns out to be constant in the same region where the distribution function is thermal.
(iv) The DM halos can be consistently considered as being in **Local Thermal Equilibrium** with a temperature

\[
T(r) = T_0 \quad \text{constant for } \ r < 3 \ r_h,
\]

and

\[
T(r) = m \ v^2 (r) / 3
\]

for \( 3 \ r_h < r < R_{\text{viriel}} \),

which slowly decreases with \( r \).

That is to say, for \( r < R_{\text{viriel}} \),

the DM halo is a **Self-Gravitant Thermal Gaz** without collisions.

(v) In the external halo region \( T(r) \) follows nicely the decreasing of the squared circular velocity
The DM in the halos of galaxies is thermalized

- All these results show robustly that the DM self-gravitating gas can thermalize in despite of being collisionless:
  - This is due to the gravitational interaction between the DM particles and to the fact that this is an ergodic system.
  - The collisionless self-gravitating gas is an isolated system which is not integrable.
  - Namely, the particle trajectories explore ergodically the constant energy manifold in phase-space, covering it uniformly according to precisely the microcanonical measure and yielding to a thermal situation.
Physically, these phenomena are clearly understood:

In the inner halo region the density is higher than beyond the halo radius. The gravitational interaction in the inner region is strong enough and thermalizes the self-gravitating gas of DM particles while beyond the halo radius the particles are too dilute to thermalize, namely, although they are virialized, they had not enough time to accomplish thermalization.
The DM in the galaxy halos is thermalized II

- Virialization always starts before than thermalization.
- In the process of thermalization there is an energy transfer flow of potential energy into kinetic energy.
- Clearly, in the outside halo region we find that the kinetic energy is lower than in the inside the region thermalization is already achieved.
- And All these results are consistent with the result found: The local temperature $T(r)$ in the outside halo region is lower than the temperature inside the halo region where thermalisation is achieved.
Self-interacting dark matter becomes disfavored

Dark matter even darker than once thought

Hubble & Chandra show that dark matter interacts with itself even less than previously thought, and narrow down the options for what dark matter might be.

Good News for WDM

(« Options to CDM »: WDM and self-interacting DM)
Collisions between galaxy clusters provide a test of the non-gravitational forces acting on dark matter. Previously: Dark matter’s lack of deceleration in the ‘bullet cluster collision’ constrained its Self-interaction DM cross-section \( /m < 1.25 \text{ cm}^2/\text{g} \) (68% CL)

Using the Chandra and Hubble Space Telescopes 72 collisions have now been observed. Combining these measurements statistically, imply:

1. The existence of dark mass at 7.6 sigma significance.
2. Self-interaction DM cross-section \( /m < 0.47 \text{ cm}^2/\text{g} \) (95% CL) → strongly disfavoring the proposed self-interacting DM models
Observations that do not presuppose the existence of dark matter show that clusters of galaxies with $10^{14} \, M_{\text{sun}}$ contain only 3.2% of their mass in the form of stars.

30 systems, mostly between redshift $0.2 < z < 0.6$ plus two at $z > 0.8$, containing 72 pieces of structure in total

The EXISTENCE of DARK MATTER is Reaffirmed:
Figure 1: Cartoon showing the three components in each piece of substructure, and their relative offsets, illustrated by black lines. The three components remain within a common gravitational potential, but their centroids become offset due to the different forces acting on them, plus measurement noise. We assume the direction of motion to be defined by the vector from the diffuse, mainly hydrogen gas (which is stripped by ram pressure) to the galaxies (for which interaction is a rare event). We then measure the lag from the galaxies to the gas $\delta_{SG}$, and to the dark matter in a parallel $\delta_{SI}$ and perpendicular $\delta_{DI}$ direction.
Le suivi d'une collision galactique au moyen du Très Grand Télescope de l'ESO et du Télescope Spatial Hubble du consortium NASA/ESA a permis de collecter des informations sur la matière noire.

En combinant les données du VLT de l'ESO au Chili aux images acquises par le télescope spatial Hubble, la collision simultanée de quatre galaxies au sein de l'amas Abell 3827 a été étudiée.

Elle a notamment été en mesure de localiser la matière contenue au sein de ce système et de comparer la distribution de matière noire aux positions occupées par les galaxies lumineuses.

A SUIVRE....
Positron excess in cosmic rays are not related to DM physics but to astrophysical sources and astrophysical mechanisms and can be explained by them.
DARK MATTER FIRMELY EXISTS WITH A VERY CLEAR MODEL INDEPENDENT STATUS FROM LSS and SSS OBSERVATIONS:

NO CDM: DARK MATTER IS NOT COLD (nor GeV DM, nor TeV DM...)
NO WIMPs DM  NO ANNIHILATING DM
NO SELF-INTERACTING DM (which is variation of CDM)

NO BOSONIC DM. NO BOSE EINSTEIN CONDENSATE DM
(NO QUANTUM BOSONIC WAVE FUNCTION DM)
NO AXION DM: DARK MATTER IS NOT BOSONIC.

DM IS WARM: keV scale mass: O(keV) means between 2 and 9 keV
DM is FERMIONIC. DM is a Fermion with mass in the keV scale
Therefore, the QUANTUM aspects of DM must be taken into account
MANY PARTICLE PHYSICS CANDIDATES: ex keV Sterile Neutrino

GRAVITATION IS NEWTONIAN IN GALAXIES and GR in the LSS UNIVERSE. NO MOND.
EXTENSION OF GRAVITY at the PLANCK SCALE but NOT at LARGE SCALES.
WARM DARK MATTER REPRODUCE

→ OBSERVED GALAXY DENSITIES AND VELOCITY DISPERSIONS

→ SOLVES the OVERABUNDANCE ("satellite") PROBLEM

→ OBSERVED SURFACE DENSITY VALUES OF DARK MATTER DOMINATED GALAXIES

→ OBSERVED GALAXY CORED DENSITY PROFILES: QUANTUM MECHANICS
• **WDM OVERALL CONCLUSION**

• To conclude, we find it is highly remarkable that in the context of warm dark matter, the quantum description provided by this semiclassical framework, *(quantum WDM and classical gravitation)*, **is able to reproduce such broad variety of galaxies.**

• The resulting **galaxy, halo radius, galaxy masses and velocity dispersion are fully consistent with observations for all different types of galaxies.** Fermionic WDM treated quantum mechanically, as it must be, is able to reproduce the observed galactic cores and their sizes. In addition, **WDM simulations produce the right DM structures in agreement with observations for scales > kpc.**
Baryons have not been included in this study. This is fully justified because on one hand dwarf compact galaxies are composed today 99.99% of DM, and on the other hand the baryon fraction in large galaxies can reach values up to 1 - 3%.

Since Fermionic WDM by itself produces galaxy main properties and structures in agreement with observations for all types of galaxies, masses and sizes, the effect of including baryons is expected to be a small correction to these pure WDM galaxy structural results, consistent with the fact that dark matter is in average six times more abundant than baryons.
WDM Thomas-Fermi Galaxy Theory with SMBH

de Vega & Sanchez, 2015
• Science is built up with facts,
  • as a house is with stones.
• But a collection of facts is no more a science
  • than a heap of stones is a house.
  -- Henri Poincaré
• La science est construit avec des faits,
  • ainsi comme une maison est construite
  • avec des pierres.
• Mais une collection de faits n’est pas une science,
  ainsi comme un tas de pierres n’est pas une maison.

ANTIMATTER IN SPACE - AMS on board ISS Alpha Magnet Spectrometer
Planck and Dark Matter, Dec2014, 2015

**DM annihilation est absente: OK.** Sur cet aspect, les données ne laissent pas d'ambiguïté possible: Souvenez-vous:
Depuis plusieurs années nous avons toujours prédit, dit, et redit qu'il n'y a pas de DM annihilation importante et que le positron excès (Pamela, FERMI, AMS-02, etc.) n'est pas du a DM annihilation mais aux sources/ phénomènes astrophysiques: c'est dans nos slides., voir Programme 2014 chalonge par exemple http://chalonge.obspm.fr/Programme2014.htmlEt ceci est de plus, un autre résultat négatif pour les modèles DM des Wimps, comme nous l'avons toujours dit.
• Why No Experimental Detection of the DM particle has been reached so far?

Because:

• All experimental searches for DM particles are dedicated to CDM: wimps of $m > 1$ GeV,

• While the DM particle mass is in the keV scale.

• Moreover, past, present and future reports of signals of such CDM experiments cannot be due to DM because of the same reason.

• The inconclusive signals in such experiments should be originated by phenomena of other kinds.

• In addition, such signals contradict each other supporting the idea that they are unrelated to any DM detection.
Dark Matter Experiment Has Detected Nothing, Researchers Say Proudly

- They found no sign of WIMPS signals, beyond the expected background noise.
- The experiment did so at far better sensitivities than any such experiment before it.

Sterile neutrinos and CMB fluctuations

CMB data give the effective number of neutrinos, $N_{\text{eff}}$. $N_{\text{eff}}$ is related in a subtle way to the number of active neutrinos (3) plus the number of sterile neutrinos.

Planck result: $N_{\text{eff}} = 3.5 \pm 0.5$ (95%; P+WP+highL+$H_0$+BAO)

Entropy conservation determines the contributions to $N_{\text{eff}}$.

WDM sterile neutrino contribution at recombination

$$\Delta N^{WDM} = \left( \frac{T_d}{T_{rc}} \right)^4 = \left[ \frac{g_{rc}}{g(T_d)} \right]^{4/3}.$$  

At recombination $g_{rc} = 29/4$.

WDM decouples early at $T_d$ beyond the Fermi scale.

The number of UR degrees of freedom at decoupling $g(T_d)$ includes all SM particles and probably beyond.

$g_{SM} = 427/4$ , $g_{MSSM} = 915/4$,

$$\Delta N_{SM}^{WDM} = 0.02771 \ldots , \quad \Delta N_{MSSM}^{WDM} = 0.01003 \ldots$$

Too small to be measurable at present!

Conclusion: Planck results say nothing about WDM. Besides, Planck results are compatible with one or two eV sterile neutrinos (see e.g. G. Steigman, 1303.0049).
Recent News on Cosmological Observables

Before 2013: Hubble constant $H_0 = 73.8 \pm 2.4 \frac{\text{km}}{\text{s}} \frac{1}{\text{Mpc}}$ from direct observations of Cepheids by HST, $\Omega_m = 0.27 \pm 0.03$. A G Riess et al. ApJ 730, 119 (2011).

Planck 2013: $H_0 = 67.3 \pm 1.2 \frac{\text{km}}{\text{s}} \frac{1}{\text{Mpc}}$. $\Omega_m = 0.32 \pm 0.02$.

Planck assumed here only three massless neutrinos and no sterile neutrinos $\nu_s$.

There is today strong evidence for $\nu_s$ with $m_s \sim \text{eV}$ from short baseline experiments (reactors, MiniBoone, LSND).

Adding one $\nu_s$ yields:

$H_0 = 70 \pm 1.2 \frac{\text{km}}{\text{s}} \frac{1}{\text{Mpc}}$. $\Omega_m = 0.30 \pm 0.01$ for $m_s = 0.4 \text{ eV}$.

These values for $H_0$ and $\Omega_m$ are compatible with the direct astronomical measurements.

Planck and the cosmological parameters

La valeur Neff est très importante et corrélée aux autres paramètres cosmologiques.

Planck a refait l'analyse des données 2014/2015 avec les mêmes priors (a priori) que en 2013 : ils ont donc très peu des corrections aux paramètres cosmologiques par rapport à Planck 2013 et donc ils ont un Neff compatible avec 3 neutrinos et les mêmes problèmes 2013 pour H_0, pour la proportion de dark énergie et pour the dark matter proportion, pour sigma_8, etc. car ils sont tous corrélés.

Trop haute oméga DM (of about 26-27 %), une trop basse oméga lambda (68%) et une trop basse H_0 pour n'arriver qu'à Neff compatible avec 3 neutrinos.... et donc ils ont les mêmes qu’avant.
Planck and Neutrinos

• At early times: CMB sensitive to radiation. The radiation density other than photons is described by the parameter \textbf{Neff}: \( \text{rad} = C(\text{Neff}) \text{ photons} \).

• At late times: CMB sensitive to neutrino masses.

• The Priors in the Planck analyse:
  • Standard value for \( \text{Neff} = 3.046 \), 3 active neutrinos:
    \( \Sigma m_\nu = 0.06 \text{ eV} \) (1 massive, the other massless).

• This is the source of the conflict with the values of \( H_0 \), lensing and clusters (sigmabar8).
Planck and Neutrinos. 2

- Une analyse plus fine que celle fait par Planck sur les données Planck 2013 a été faite par plusieurs groups différents et donne Neff compatible avec 4 neutrinos = les 3 actifs connus + 1 stérile et les paramètres cosmologiques sans tensions avec les autres observations.

- Donc, les données Planck 2014 pourront être a nouveau ré-analyses par d'autres teams et Neff et les valeurs des paramètres cosmologiques corrigés.
Planck and Neutrinos.3

- En fait le CMB est sensible à la valeur de sigma8 très tôt dans l'Univers, à redshift =1100 (moment où l'Univers devient transparent 380 000 après le Big Bang), alors que les amas qui se forment tard, mesurent la valeur de sigma8 à z~1 (il y a 8 milliards d'années).

- La relation entre ces deux valeurs dépend de la croissance des structures. Or celle-ci est ralentie par les neutrinos, d'autant plus qu'ils sont massifs. Dans le modèle standard de la cosmologie, la somme des masses des neutrinos est aujourd'hui fixée à une valeur minimale de 0.06 eV (correspondant à la mesure de la somme des masses d'oscillation déterminée par les expériences de neutrinos et en considérant que la masse du neutrino le plus léger est nul).

- Le désaccord sur sigma8 entre le CMB et amas peut être résolu si on permet que la somme des masses des neutrinos soit comprise entre 0.2 et 0.3 eV. Cependant, cette valeur haute doit être confrontée aux contraintes posées par les BAO et l'analyse des forêts Lymann-Al h (4) i i à d'ê l i 0 15 V
Sterile Neutrinos $\nu$

Rhenium and Tritium beta decay (MARE, KATRIN).

[Other possibility to detect a sterile $\nu_s$: a precise measure of nucleus recoil in tritium beta decay.]

Conclusion: the empty slot of right-handed neutrinos in the Standard Model of particle physics can be filled by keV-scale sterile neutrinos describing the DM.

An appealing mass neutrino hierarchy appears:

- Active neutrino: $\sim$ mili eV
- Light sterile neutrino: $\sim$ eV
- Dark Matter: $\sim$ keV
- Unstable sterile neutrino: $\sim$ MeV...
The Lyman-alpha forest flux power spectrum, compared to predictions for cold dark matter (green) and warm dark matter (red). The amplitude of the power spectrum at small scales (large values of k) favors cold dark matter.
