Ultra-High Energy Cosmic Rays

Dmitri Semikoz APC, Paris

Overview:

- UHECR measurements
- Acceleration of UHECR in astrophysical sources
- Propagation of UHECR: energy losses, magnetic fields
- UHECR spectrum and GZK cutoff
- Theoretical models and composition

Overview:

- UHECR arrival directions, their sources and galactic and extragalactic magnetic field
- Correlations of UHECR E>56 EeV with LSS
- Particle physics and UHECR
- Multi-messenger observations with UHECR
- Conclusions

INTRODUCTION

Measurements of UHECR

UHECR measurement

- Depth of atmosphere is 1000 g/cm²
- Proton of 10²⁰ eV energy interact within 60-80 g/ cm². Center mass energy is 300 TeV: much larger then LHC!
- Shower develops with final number 10¹⁰⁻¹¹ of low energy particles.

Parameters to measure:

- Energy of primary particle
- Arrival direction.
- Type of primary particle (proton, nuclei, photon, neutrino, new particle)
- Properties of primary particle: total cross section.

Detection of showers on ground

- Ground array measure footstep of the shower. Final particles at ground level are gamma-rays, electrons, positrons and muons.
- Typically 10¹⁰⁻¹¹ photons, electrons and positrons in area 20-50 km². It is enough to have detectors with area of few m² per km². Number of low energy particles is connected to primary energy.
- Space/time structure of signal give information on arrival direction.
- Number of muons compared to number of electrons give information on primary particle kind.

Detection of shower development in atmosphere

- Fly's Eye technique mesure fluorescence emision of N₂ by collection of mirrors: shape of the shower.
- Total amount of light connected to energy of primary particle.
- Time structure of signal gives information on arrival direction.
- Depth in atmosphere with maximum signal give information on primary particle kind.

HiResl

HiRes2

Shower structure: theoretical uncertanty

 Extrapolation of accelerator data to high energies with different approaches can give uncertainty up to 30 % in energy estimate for same shower and 100% important for chemical composition study.

AGASA

- AGASA covers an area of about 100 km² and consists of 111 detectors on the ground (surface detectors) and 27 detectors under absorbers (muon detectors). Each surface detector is placed with a nearest-neighbor separation of about 1 km.
- Operated 1993- 2003.

Akeno Giant Air Shower Array

High Resolution Fly's Eye: HiRes

- HiRes 1 and HiRes 2 sit on two small mountains in western Utah, with a separation of 13 km.
- HiRes 1 has 21 three meter diameter mirrors which are arranged to view the sky between elevations of 3 and 16 degrees over the full azimuth range;
- HiRes 2 has 42 mirrors which image the sky between elevations of 3 and 30 degrees over 360 degrees of azimuth.
- Operated in stereo mode 1999-2006.

Correlations with local LSS

Prescription of blind test

- Based on 15 events E>56 EeV period January 1, 2004 - May 28, 2006
- 12th Catalog of AGN's by Veron
- Z<=0.018 or R<=75 Mpc 472 objects</p>
- PAO data with ICRC T5 E>=56 EeV Herald v4
- Search of correlations in 3.1 degree angle from AGN's. Within this angle P_{chance}=0.21
- Running prescription until P=0.01 or up to 34 events
- Status: passed 6/8 May 2007
- At August 31, 2007 8/13 P=1.6e-3

Arrival directions for E>57 EeV in Auger

Paris, June 4 2009, Ultra-High Energy Cosmic Rays

Doublet – at Cen A - real source? 2 sigma at the moment

Cen A: radio galaxy

Paris, June 4 2009, Ultra-High Energy Cosmic Rays

Cen A

- Radio galaxy with AGN located at 4 Mpc from our galaxy: extremely nearby !!!
- Typical distance between radio galaxies is 20-40 Mpc

 Most nearby AGN: typical distance between AGN's is 10 Mpc (if not in clusters)

Cen A: Auger ICRC 2009

Fig. 3. Left: The cumulative number of events with $E \ge 55$ EeV as a function of angular distance from Cen A. The average isotropic expectation with approximate 68% confidence intervals is shaded blue. *Right:* The histogram of events as a function of angular distance from Cen A. The average isotropic expectation is shaded brown.

Statistics with Galactic plane cut

- Z<=0.018 R=75 Mpc: 425 AGN
 |b|>12 degrees
- 6 events in Galactic plane only one correlate
- Out of Galactic plane 21 event /19 correlate 90%.
- Only new events: 11/9 correlate P=0.0002

SUMMARY of Auger correlation study 2007:

- Evidence that UHECR sky is anisotropic above GZK cutoff
- 3 degree angle mean that magnetic fields are not very large + <Z> is not very large ? Contradict composition!
- Independent confirmation of GZK cutoff from correlations with NEARBY sources.
- AGN's can be sources or tracers of sources in local LSS
- ONLY PROTONS from AGN's: Energy scale has to move up E->E+30% Warning: There is no signal from Virgo cluster, 2-3 sigma
- New data?

Source in magnetized region

Particle physics at ultra-high energies

Number of muons and energy scale

Relative number of muons

we need in 1.5 times more muons as compared to QGSJET-II model: Heavier then Fe or wrong model prediction

Composition study: depends on hadronic interaction models

Paris, June 4 2009, Ultra-High Energy Cosmic Rays

LHC-CR interplay

Calibration of the models at high energy is mandatory

14 TeV in the center of mass $E_{lab}=10^{17} \text{ eV} (E_{lab}=E_{cm}^2/2 \text{ m}_P)$

Major LHC detectors (ATLAS, CMS, LHCB) will measure the particles emitted in transverse directions

LHCf is a tool to calibrate MC code to energy relevant for CR physics. It will cover the very forward part May be also Heavy Ion runs? Paris, June 4 2009, Ultra-High Energy Cosmic Rays

Two independent detectors on both side of IP1

- ✓ Redundancy
- Background rejection (especially beam-gas)

Conclusions

- Cutoff in UHECR spectrum exist. UHECR come from astrophysical sources. Open questions:
 - □ Cutoff from acceleration or/and cutoff from propagation.
 - □ Composition: protons or/and nuclei?
- November 9, 2007: Evidence that sources are in local LSS.
- A lot of astrophysics can be done: Galactic and extragalactic magnetic fields, individual sources of UHECR, acceleration mechanism, etc. Larger detectors needed (Auger North, JEM-EUSO, etc.)!
- Input from LHC needed to reduce uncertainty in hadronic models: energy determination and composition of UHECR. Definitely revision of calculations with high-energy interactions.
- Secondary photons and neutrinos can give additional information on sources when they will be detected
